## Overview

---

The organization of a microgrid control system is structured into a hierarchy with three distinct levels: primary, secondary, and tertiary control. NLR develops and evaluates microgrid controls at multiple time scales. A microgrid is a group of interconnected loads and. This distribution network is designed to possess desired characteristics such as reliability, security, stability and sustainability of energy. Distributed Generation (DG) employs various dispersed energy sources to generate electric power reliably and close to the load that is being served. These levels are specifically designed to perform functions based on the MG's mode of operation, such as. A MG must meet four conditions: (a) integrate distributed energy resources and loads, (b) be capable of being disconnected (in parallel) from the power grid, (c) comprise the local electric power system, and (d) be purposefully scheduled [2].
