

# **Will wind turbine blades deform**

## Overview

---

Wind turbine blades are getting bigger and longer — some now exceed 150 meters in length. By accounting for blade deformation, the computationally-efficient model will allow for the safe design of bigger blades. Under normal working conditions, these massive blades can deform by more than ten. The aerodynamic performance of a wind turbine rotor blade depends on the geometry of the airfoils used. The airfoil shape can be affected by elastic deformations of the blade during operation due to structural loads. " They decide how much wind gets converted into rotational force — and ultimately, electricity.
