Wind turbine asynchronous generator

Overview

Asynchronous generators, also known as induction generators, are predominantly used in wind turbines due to their robustness, cost-effectiveness, and ability to generate reactive power. They are typically used where control of the prime mover is not possible, such as wind. A DC wind generator system consists of a wind turbine, DC generator, an insulated gate bipolar transistor (IGBT) inverter, a transformer, a controller, and a power grid. Induction generators (asynchronous generators) designed with lower rotor R to reduce losses and machine slip.) Increase prime mover mechanical power input until $n_r > n_s$. The Simple Turbine block converts wind speed to turbine output power by a simple output power versus wind speed characteristic.
